NES AI FINANCE & INSURANCE INTELLIGENCE PLATFORM

Backup, Restore & Data Retention Plan

Document ID: NES-DATAOPS-016 | **Version:** 1.0

Build approach: Cline-assisted development • Local-first Windows application

Scope: Personal research, paper trading and insurance document assistance

Local data recovery and deletion semantics

1. Backup scope

- Database records and user preferences.
- Policy document files and their metadata, if real documents are later enabled.
- Saved research and generated reports.
- Configuration references, excluding secrets by default.
- Versioned schema and restore instructions.

2. Backup policy decisions

- Choose backup location and retention based on the user's privacy needs.
- Document whether backups are encrypted and how keys are managed.
- Do not silently sync personal documents to a cloud location.
- Warn if a backup omits files or sensitive records.
- Keep backups separate from the primary data directory where feasible.

3. Restore workflow

Select backup → validate archive and manifest → confirm destination → restore database and files → run integrity checks → show result and any missing items.

4. Deletion and retention

- Define what delete means for database entries, local files, derived reports and backups.
- Provide confirmation for permanent deletion.
- Do not promise complete deletion from backups unless the process supports it.
- Set retention for diagnostic logs and temporary OCR files.

5. Test plan

- Restore to a clean test directory.
- Verify document checksums or file counts where appropriate.
- Check foreign-key relationships and record counts.
- Test missing/corrupt backup handling.
- Document recovery steps for database and file-storage failures.

6. Acceptance

Do not use the application as the only storage location for important policy documents until backup and restore have been tested.
